Soluble chromophores having improved solubilising groups

The present Application relates to novel soluble chromophores having removable solubilising oxy-, thio- or amino-alkylene-oxycarbonyl groups. Those compounds have improved properties, especially a surprisingly higher solubility. In dissolved form those chromophores can be incorporated very readily into substrates in high concentrations and can then be converted back into the corresponding insoluble pigments with an especially high degree of conversion. Those groups can also be introduced into chromophores that cannot be reacted, or react only unsatisfactorily, with known groups.

EP 648 770 and EP 648 817 disclose soluble, carbamate-group-containing chromophores that can be converted into the corresponding pigments by heating to relatively high temperatures, which results in the removal of the carbamate radicals. Among other numerous combinations, C<sub>1</sub>-C<sub>4</sub>alkylthio-C<sub>1</sub>-C<sub>14</sub>alkylenecarbamate radicals are also possible.

Quinophthalone carbonates having limited solubility are known from US 5 243 052 and can be used in heat-sensitive registration systems.

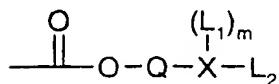

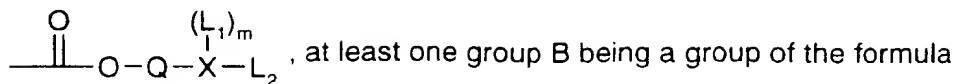

It has now been found that soluble chromophores having markedly improved properties are obtained when oxy-, thio- or amino-alkylene-oxycarbonyl groups are used as solubilising groups.

The present invention accordingly relates to compounds of formula A(B)<sub>x</sub> (I), wherein x is an integer from 1 to 8,

in an aprotic organic solvent in the presence of a base as catalyst, advantageously at temperatures of from 0 to 120°C, preferably from 10 to 100°C, for from 2 to 80 hours.

The molar ratio in each particular case is governed by x, that is to say the number of radicals B to be introduced. The dicarbonate is advantageously used in slight excess.

Suitable aprotic organic solvents are, for example, ethers, such as tetrahydrofuran or dioxane, or glycol ethers, such as ethylene glycol methyl ether, ethylene glycol ethyl ether, diethylene glycol monomethyl ether or diethylene glycol monoethyl ether, and also dipolar aprotic solvents, such as acetonitrile, benzonitrile, N,N-dimethylformamide, N,N-dimethylacetamide, nitrobenzene, N-methylpyrrolidone, halogenated aliphatic or aromatic hydro-

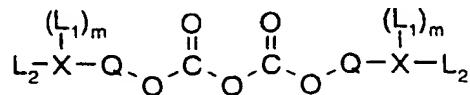

carbons, such as trichloroethane, benzene, or benzene substituted by alkyl, alkoxy or by halogen, such as toluene, xylene, anisole or chlorobenzene, or aromatic N-heterocycles, such as pyridine, picoline or quinoline. Preferred solvents are, for example, tetrahydrofuran, N,N-dimethylformamide and N-methylpyrrolidone. The mentioned solvents can also be used in the form of mixtures. It is advantageous to use from 5 to 20 parts by weight of solvent to 1 part by weight of reactant.

Bases suitable as catalyst are, for example, the alkali metals themselves, such as lithium, sodium or potassium and the hydroxides and carbonates thereof, or alkali metal amides, such as lithium, sodium or potassium amide, or alkali metal hydrides, such as lithium, sodium or potassium hydride, or alkaline earth or alkali metal alcoholates that are derived especially from primary, secondary or tertiary aliphatic alcohols having from 1 to 10 carbon atoms, such as, for example, lithium, sodium or potassium methanolate, ethanolate, n-propanolate, isopropanolate, n-butanolate, sec-butanolate, tert-butanolate, 2-methyl-2-butanolate, 2-methyl-2-pentanolate, 3-methyl-3-pentanolate, 3-ethyl-3-pentanolate, and also organic aliphatic, aromatic or heterocyclic N-bases including, for example, diazabicyclooctene, diaza-bicycloundecene and 4-dimethylaminopyridine, and trialkylamines, for example trimethylamine or triethylamine. It is also possible, however, to use a mixture of the mentioned bases.

Preference is given to the organic N-bases, such as, for example, diazabicyclooctane, diaza-bicycloundecene and especially 4-dimethylaminopyridine.

The reaction is carried out especially at temperatures of from 18 to 40°C, that is to say preferably at room temperature, and under atmospheric pressure.

The dicarbonates of the formula

suitable for the preparation of the compounds of formula I according to the invention can be prepared analogously to generally known methods. Most of the chemicals required for that

purpose are known. Many of them are commercially available and all of them can be prepared in accordance with methods known *per se*.

The compounds of formula I according to the invention are excellently suitable as fluorescent dyes for the mass-colouring of high-molecular-weight organic material.

Examples of suitable high-molecular-weight organic materials that can be coloured using the compounds of formula I according to the invention are vinyl polymers, e.g. polystyrene, poly- $\alpha$ -methylstyrene, poly-p-methylstyrene, poly-p-hydroxystyrene, poly-p-hydroxyphenylstyrene, poly(methylacrylate) and poly(acrylamide) and also the corresponding methacrylic compounds, poly(methyl maleate), poly(acrylonitrile), poly(methacrylonitrile), poly(vinyl chloride), poly(vinyl fluoride), poly(vinylidene chloride), poly(vinylidene fluoride), poly(vinyl acetate), poly(methylvinyl ether) and poly(butylvinyl ether); novolaks derived from C<sub>1</sub>-C<sub>6</sub>-aldehydes, e.g. formaldehyde and acetaldehyde, and a dinuclear, preferably mononuclear, phenol that is unsubstituted or substituted by one or two C<sub>1</sub>-C<sub>9</sub>alkyl groups, by one or two halogen atoms or by a phenyl ring, such as, for example, o-, m- or p-cresol, xylene, p-tert-butylphenol, o-, m- or p-nonylphenol, p-chlorophenol or p-phenylphenol, or a compound having more than one phenolic group, e.g. resorcinol, bis(4-hydroxyphenyl)methane or 2,2-bis(4-hydroxyphenyl)propane; polymers derived from maleimide and/or maleic anhydride, e.g. copolymers of maleic anhydride and styrene; poly(vinylpyrrolidone), biopolymers and derivatives thereof, e.g. cellulose, starch, chitin, chitosan, gelatin, zein, ethylcellulose, nitrocellulose, cellulose acetate and cellulose butyrate; natural resins and synthetic resins, e.g. rubber, casein, silicone and silicone resins, ABS, urea- and melamine-formaldehyde resins, alkyd resins, phenol resins, polyamides, polyimides, polyamide/imides, polysulfones, polyether sulfones, polyphenylene oxides, polyurethanes, polyureas, polycarbonates, polyarylenes, polyarylene sulfides, polyepoxides, polyolefins and polyalkadienes. Preferred high-molecular-weight organic materials are, for example, cellulose ethers and esters, such as ethylcellulose, nitrocellulose, cellulose acetate or cellulose butyrate, natural resins or synthetic resins, such as polymerisation or condensation resins, such as aminoplasts, especially urea- and melamine-formaldehyde resins, alkyd resins, phenoplasts, polycarbonates, polyolefins, polystyrene, polyvinyl chloride, polyamides, polyurethanes, polyesters, ABS, polyphenylene oxides, rubber, casein, silicone and silicone resins, individually or in admixture.

The mentioned high-molecular-weight organic compounds may be present individually or in mixtures in the form of plastics, melts or in the form of spinning solutions, paints, coating compositions or printing inks. According to the intended use it has proved advantageous to use the compounds of formula I according to the invention as toners or in the form of a preparation.

The compounds of formula I according to the invention are especially suitable for the mass-colouring of polyvinyl chloride and especially polyolefins, such as polyethylene and polypropylene, as well as of paints and also of powder coating compositions, printing inks and coating compositions.

The compounds of formula I according to the invention can be used in an amount of from 0.01 to 30 % by weight, preferably from 0.1 to 10 % by weight, based on the high-molecular-weight organic material to be coloured.

The colouring of high-molecular-weight organic substances with the compounds of formula I according to the invention is carried out, for example, by mixing the compound of formula I, optionally in the form of a master batch, into those substrates using roll mills or mixing or grinding apparatus. The coloured material is then brought into the desired final form according to procedures known *per se*, such as calendering, compression moulding, extrusion moulding, coating, casting or injection-moulding. It is often desirable for the purpose of producing non-rigid mouldings or reducing the brittleness thereof to incorporate so-called plasticisers into the high-molecular-weight compounds before shaping. There may be used as plasticisers, for example, esters of phosphoric acid, phthalic acid or sebacic acid. The plasticisers can be incorporated into the polymers before or after the incorporation of the compounds of formula I according to the invention. In order to obtain different colour shades it is also possible to add to the high-molecular-weight organic substances, in addition to the compound according to the invention, any desired amounts of fillers or other colour-imparting constituents, such as white, coloured or black pigments.

For the colouring of paints, coating compositions and printing inks, the high-molecular-weight organic materials and the compounds of formula I according to the invention, optionally together with additives, such as fillers, pigments, siccatives or plasticisers, are finely

dispersed or dissolved in a common organic solvent or solvent mixture. It is also possible for the individual components to be dispersed or dissolved separately, or for several components to be dispersed or dissolved together, and only then for all the components to be combined.

In colourings, for example of polyvinyl chloride or polyolefins or in printing inks, the compounds of formula I according to the invention are distinguished by good general properties, such as good migration-stability and light- and weather-fastness, but especially by their unexpectedly high fluorescence.

Very great importance is attached, however, to the conversion of the soluble chromophores according to the invention that have been incorporated into a substrate into the corresponding pigments of the formula  $A(H)_x$ . This can be achieved most simply by thermal treatment (heating to temperatures of from 50 to 250°C, preferably from 100 to 200°C, according to the pigment) of the solids, solutions or dispersions comprising the soluble compounds according to the invention in organic or aqueous media, polymer solutions or melts. This allows the colouring of paints, printing inks, plastics, especially also in fibre form, heat-sensitive registration systems, inks for ink-jet printing, colour tapes for thermal transfer printing onto smooth or woven receiver substrates, and very specifically also in light-sensitive compositions, for example negative or positive resist formulations, giving an overall improvement in properties, such as purity, colour strength, brilliance and transparency, and also allows interesting applications in analysis.

The invention therefore relates also to high-molecular-weight organic material comprising in its mass a pigment of the formula  $A(H)_x$ , produced *in situ* by thermal degradation of a soluble compound of formula I, to a thermo-, photo- or chemo-sensitive recording material, and to an ink for ink-jet printing, a colour tape for thermal transfer printing or a light-sensitive negative or positive resist composition, each comprising a soluble compound of formula I.

Inks for ink-jet printing, colour tapes for thermal transfer printing, thermo-, photo- and chemo-sensitive recording materials and also light-sensitive negative or positive resist compositions are well known to the person skilled in the art.

It has also been found that in the case of certain compounds of formula I the thermal treat-

ment comprising heating to temperatures of from 100 to 200°C, preferably from 105 to 120°C, may result in crystal modification conversions of the corresponding chromophores of the formula A(H)<sub>x</sub>. If different compounds of formula I are used, it is also possible to prepare mixed crystals.

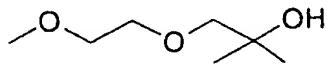

The invention therefore relates also to a process for the preparation of mixed crystals or for the crystal modification conversion of chromophores of formula A(H)<sub>x</sub> by conversion into compounds of formula I, for example in accordance with the above-mentioned process, and thermal treatment of the resulting compounds of formula I at temperatures of from 100 to 200°C.

A very special, surprising advantage of the compounds according to the invention is their extraordinarily high solubility. As a result it is possible to incorporate relatively high concentrations into a substrate, so that a higher colour intensity can be achieved. A further surprising advantage is that the conversion into the pigment is more complete than in the case of known soluble pigments, thereby improving the migration tendency after conversion into the pigment. Another surprising advantage is that soluble chromophores can be prepared from pigments that could not be reacted, or could be reacted only unsatisfactorily, with the solubilising groups known hitherto.

As a result of those improved properties, the soluble chromophores of formula I according to the invention can be used especially advantageously in compositions that are used in the preparation of structured colour formers or colour filters. The use of soluble pigment precursors in the preparation of structured colour formers or colour filters is known from EP 654 711. Those compositions comprise, for example, a soluble chromophore of formula I and a positive or negative resist resin. In particular, it is possible for resist formulations comprising soluble pigment precursors to be irradiated and developed in the desired pattern, it being possible for the soluble pigment precursor to be converted into the insoluble pigment during irradiation or development or alternatively only subsequently. The soluble pigment precursor can also be applied in the desired pattern directly to a receiving layer suitable for the purpose by means of ink-jet printing or by thermally induced diffusion. The methods disclosed in EP 654 711 are very suitable for the production of colour filters.

The following Examples illustrate the invention (unless otherwise indicated, "%" are always % by weight):

Example 1: A solution of 52.52 g of methyl iodide in 100 ml of dry diethyl ether is added dropwise to a suspension of 9.0 g of magnesium turnings in 50 ml of dry diethyl ether. After one hour at 25°C, the reaction mixture is cooled to 10°C; 75 ml of diethyl ether are added and then 135 ml of 10% hydrochloric acid are added dropwise at 10-15°C.
